

The difference between *_Rig and *_TechRig files

In this version, you will find we present 2 rig files. When you open these files, they look pretty much the same. If you are working under parallel mode, the frame rate of these 2 rigs will also work pretty much the same.

The only difference between these 2 rigs is that you can export TechRig to the game engine, while you can't do that with the general rig file. In the tech rig file, we use a joint-only hierarchy to skin bind the geometry which costs a little more calculation.

If you are working under the “DG” mode, you will find the general rig file works a few frames faster than the tech rig file. But overall DG mode works very slowly.

How to export the tech rig file to game engine?

Below is what you need to know:

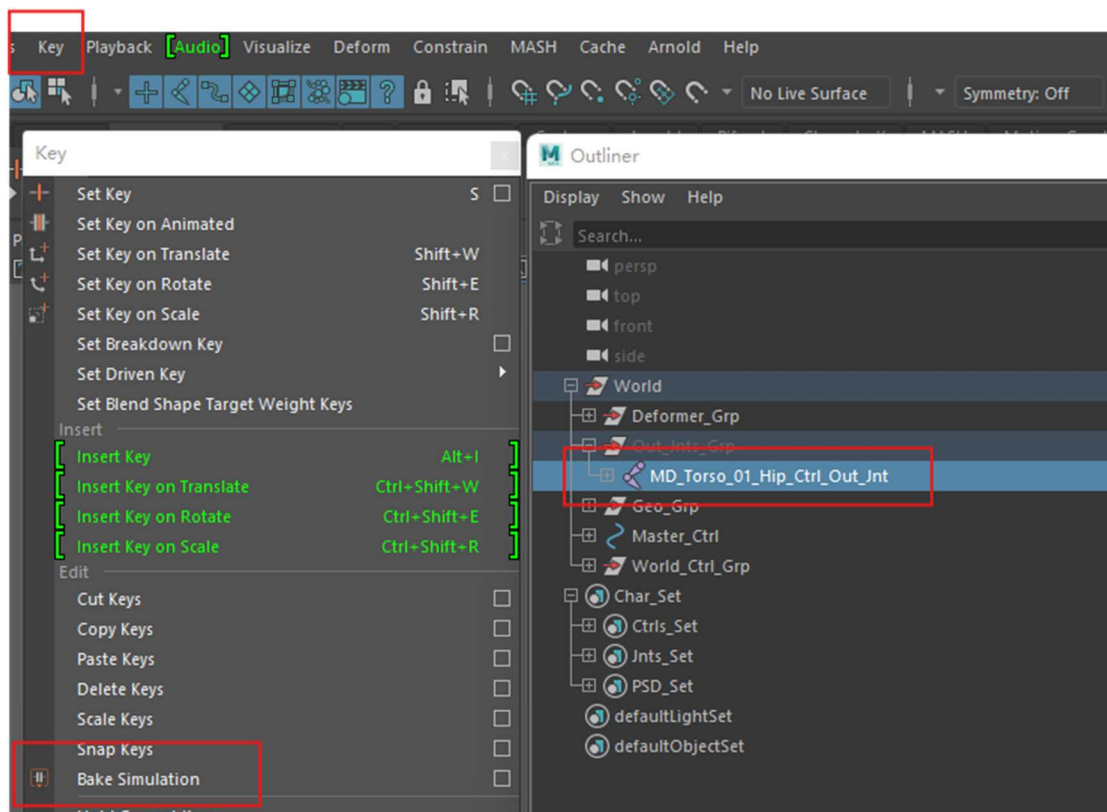

The file that Unreal or Unity can read is "FBX" format. So The key is using Maya to generate FBX files. **FBX file can only save data of geometry, joints, blendshapes, and keyframes on top of these nodes.**

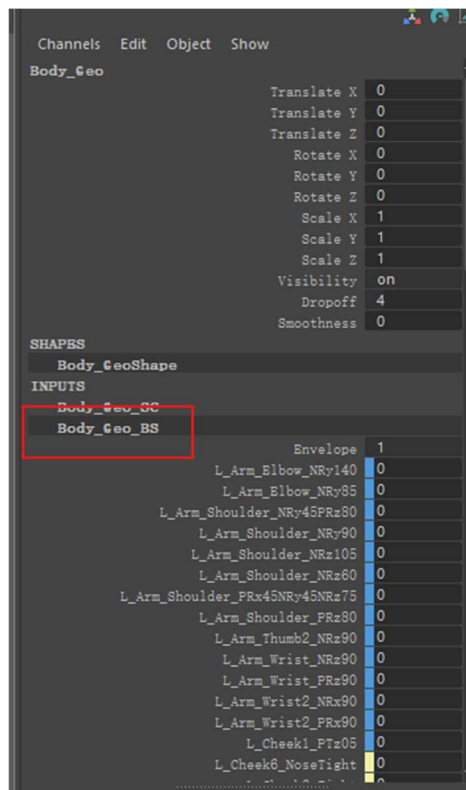

1. So we won't have a same rig work the same in the game engine as in Maya, unless we rebuild the rig logic in the game engine which could cost an insane amount of work.
2. We can only play baked animation in Game Engine. However, you can still edit the animation, but on a massive number of joints without the help of IK or any intuitive setup.
3. Therefore, in a general pipeline, **the game engine works mostly like a rendering engine**, though it can do more than that.

There are many tutorials available online showing you how to export rig to the game engine. We recommend you watch more to understand the process.

Below is a simple and general export steps:

1. Do keyframe animation as usual.
Reference the rig, pose the rig, create keyframe on top of controls, do more poses...
2. Bake animation for joints and blendshape.

3. Select joints and geometry and export as FBX format. Please make sure you turn on Animation, Bake Animation, and Deformed Models.
